SUMMARY

Applied Scientist Intern at AWS and PhD student in Computer Science at George Mason University specializing in automated reasoning, and scalable verification of deep neural networks. Lead developer of NeuralSAT, an open-source engine ranked 2nd at VNN-COMPs, with published papers at CVPR, NeurIPS, CAV, and FSE.

EDUCATION

- **PhD**, Computer Science, George Mason University, Fairfax, VA — 2022–2027 (expected)
- **MS**, Computer Science, George Mason University, Fairfax, VA — 2022–2026 (expected)
- **MS**, Electrical Engineering, Hanoi University of Science and Technology, Hanoi, Vietnam — 2019–2021

EXPERIENCE

- **Applied Scientist**, Prime Air, Amazon, *Seattle, WA* — 2026 (expected)
- **Applied Scientist Intern**, Amazon Web Services, Amazon, *Santa Clara, CA* — 2026
  - Developed SMT-based path enumeration and fuzzing for AWS compliance, achieving 100% test coverage and exposing legacy-migration divergences.
  - Built automated Java/Python to ControlsDSL migration framework with bidirectional equivalence verification, porting 40% of staging rules to production.
- **Graduate Researcher**, ROARS Lab, George Mason University, *Fairfax, VA* — 2022–present
  - Architected NeuralSAT (Python, PyTorch, CUDA), an open-source GPU-accelerated DNN verification engine; ranked 4th (2023, 2026) and 2nd (2024, 2025) at VNN-COMP.
  - Developed VeriStable (FSE'24), a DPLL-based verifier exploiting stable neurons; outperforms α-β-CROWN and NeuralSAT and solved 48 of 51 hard GDVB problems vs. 4 for the baseline (12× more).
  - Extended robustness verification to new perturbation classes with VeriS (FSE'26) and VeriDou (CVPR'26 Highlight): VeriS verifies 78% of 5,508 structural-robustness problems prior tools could not, while VeriDou exposes adversarial examples over 14,340 instances on networks prior methods claimed robust.
  - Designed APTP (NeurIPS'25), a verifier-independent proof format whose checker outperforms prior work across 16 networks and 400 problems.
  - Developed CLAD, a constrained abstract domain using a Lagrangian primal–dual method; over 8,640 instances, verifies up to 19% more properties than the best prior abstraction and 31% more on constrained properties at 5.7× the speed.
  - Built VerCa, an autoencoder robustness verifier solving 87% of latent-space properties, with zero invalid counterexamples.
  - Built ZonoGPT, an abstract domain for verifying large GPT models, up to GPT-2 medium with 300M+ parameters.
  - Built mBFV, a bound propagation method handling multi-parameter bit-flip perturbations.

SKILLS

- **Programming Languages:** Python, C/C++, MATLAB, SMTLib, Lean, PyTorch, CUDA, NumPy
- **Methods:** SAT/SMT solving, abstract interpretation, branch-and-bound, LP/MILP, reinforcement learning

AWARDS

- High Impact Grant, George Mason University — 2027
- Tinker Research Grants ($5,000 API Credits), Thinking Machines — 2026
- Outstanding PhD Student Award, George Mason University — 2026
- Highlight Paper Award [P3], CVPR — 2026
- Spotlight Paper Award [P5], NeurIPS — 2025
